#### 9. UNIT TEST

Nguyen Thi Thu Trang trangntt@soict.hust.edu.vn

#### Content

- 1. Testing overview
- 2. Unit Test
- 3. Integration Test

1

# **Testing**

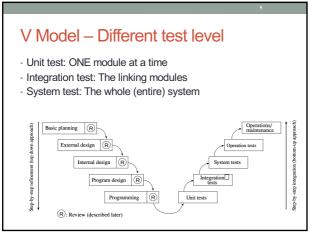

- "[T]he means by which the presence, quality, or genuineness of anything is determined; a means of trial." – dictionary.com
- A software test executes a program to determine whether a property of the program holds or doesn't hold
- □ A test *passes* [*fails*] if the property **holds** [doesn't hold] on that run

# Software Quality Assurance (QA) Testing plus other activities including

- Static analysis (assessing code without executing it)
- Proofs of correctness (theorems about program properties)
- Code reviews (people reviewing others' code)
- Software process (placing structure on the development lifecycle)
- ...and many more ways to find problems and to increase confidence

No single activity or approach can guarantee software quality

3

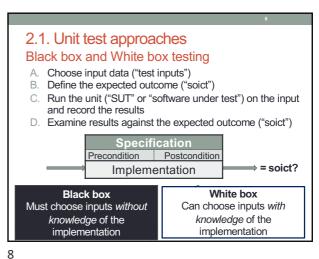

#### Test levels

- Unit Testing: Does each unit (class, method, etc.) do what it supposed to do?
  - · Smallest programming units
  - Strategies: Black box and white box testing
  - Techniques, Tools
- Integration Testing: do you get the expected results when the parts are put together?
  - · Strategies: Bottom-up, top-down testing
- System Testing: does it work within the overall system?
- Acceptance Testing: does it match to user needs?

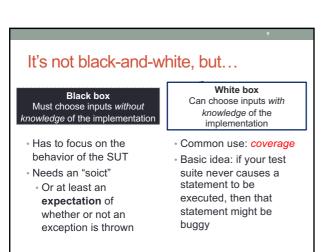

5

Unit Testing techniques

For test case design

(2.2) Test Techniques for Black Box Test
Equivalence Partitioning Analysis
Boundary-value Analysis
Decision Table
Use Case-based Test

(2.3) Test Techniques for White Box Test
Control Flow Test with C0, C1 coverage
Sequence chart coverage test

11 12

#### 2.2. Blackbox Testing Techniques 2.2.1. Equivalence Partitioning

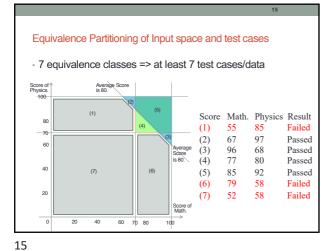

- · Create the encompassing test cases by analyzing the input data space and dividing into equivalence classes
- · Input condition space is partitioned into equivalence classes
- Every input taken from a equivalence class produces the same result

**Example: Examination Judgment Program** 

- · Program Title: "Examination Judgment Program"
- · Subject: Two subjects as Mathematics, and Physics Judgment
- Specification:
  - · Passed if
    - scores of both mathematics and physics are greater than or equal to 70 out of 100

- average of mathematics and physics is greater than or equal to 80 out of 100
- · Failed => Otherwise

14 13

**Equivalence Partitioning** Discussions and additional analysis

· Are we successful?

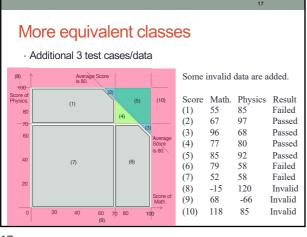

16

- · No we don't! Why?
- →One thing is missing!
- The scope of input space analyzed is not enough!
- · We must add "Invalid value" as the test data.
  - · For example, some patterns of "Invalid value".
  - (8) Math = -15, Physics = 120 (9) Math = 68, Physics = -66

Both score are invalid. Physics score is invalid.

• (10) Math = 118, Physics = 85

Math score is invalid.

# Analysis and discussions

- We tried to create encompassing test cases based on external specification.
  - · Successful? "Yes"!
- · Next question. The test cases/data are fully effective?
- We have to focus on the place in which many defects are there, don't we?
- · Where is the place ?
- → "Boundary-value analysis"

17 18

2.2. Blackbox Testing Techniques

2.2.2. Boundary-value analysis

Extract test data to be expected by analyzing boundary input values => Effective test data

Boundary values can detect many defects effectively

→E.g. mathematics/physics score is 69 and 70

The programmer has described the following wrong code:

if (mathscore > 70) {

Instead of the following correct code;

if (mathscore >= 70) {

Example: Boundary-value analysis

 Boundary values of the mathematics score of small case study:

Invalid value failed passed Invalid value
-1 0 69 70 100 101

 What about the boundary value analysis for the average of mathematics and physics?

failed passed
7980

19 20

# 2.2. Blackbox Testing Techniques2.2.3. Decision Table

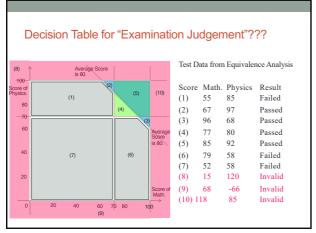

- Relations between the conditions for and the contents of the processing are expressed in the form of a table
- A decision table is a tabular form tool used when complex conditions are combined

# Example: Decision table

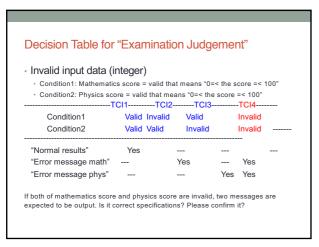

- The conditions for creating reports from employee files

Under age 30	Υ	Υ	N	N
Male	Υ	N	Υ	N
Married	N	Υ	Υ	N
Output Report 1	-	Х	-	-
Output Report 2	-	-	-	Χ
Output Report 3	Х	-	-	-
Output Report 4	-	-	Х	-

21 22

23 24

2.2. Blackbox Testing Techniques 2.2.4. Testing for Use case • E.g. Decision table for Login Results E.g. Boundary Value Analysis

25 26

# Test cases for "Log in"

- "Thành công"Mã PIN đúng
- · "Thất bại"
- Mã PIN sai và số lần sai < 3</li>
- "Khoá tài khoản"
  - Mã PIN sai và số lần sai = 3

Mã PIN đúng	Υ	Y	N	N
Số lần sai < 3	Y	N	Υ	N
"Thành công"	х	N/A	-	-
"Thất bại"	-	N/A	х	-
"Khoá tài khoản"	-	N/A	_	×

Phân tích vùng biên? Số lần sai = 2, 4 (?)

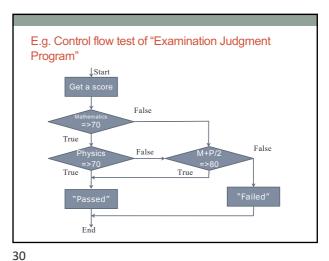

Creating test cases from use cases

- Identify all of the scenarios for the given use case
- · Alternative scenarios should be drawn in a graph fo each action
- · Create scenarios for
  - · a basic flow,
  - · one scenario covering each alternative flow,
  - · and some reasonable combinations of alternative flows
- · Create infinite loops

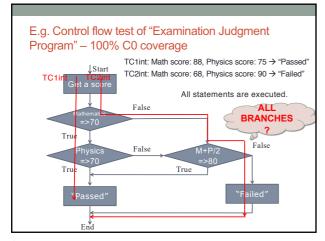

28 27

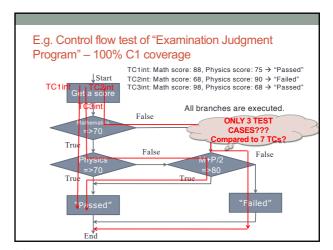

# 2.3. White Box Testing Techniques

- Test cases should cover all processing structure in code
- => Typical test coverage
  - C0 measure: Executed statements #/all statements #
  - C0 measure at 100% means "all statements are executed"
  - C1 measure: Branches passed #/all blanches #
    - C1 measure at 100% means "all branches are executed"
- => Prevent statements/blanches from being left as non-tested parts
- => Cannot detect functions which aren't implemented

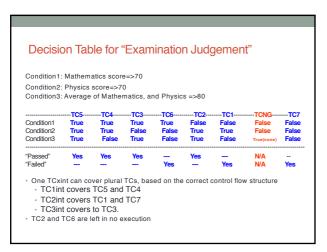

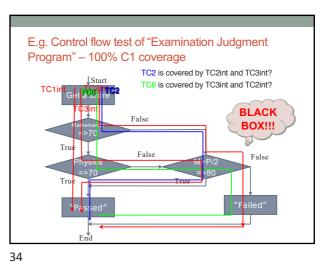

29

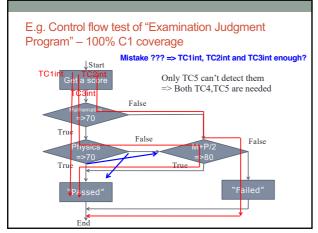

31 32

#### Data/message path test for integrated test

- Execute white box test using sequence chart for integration test.
- ⇒Execute every message path/flow
- ⇒100% message path/flow coverage
- Can apply to other data/message path/flow charts or diagrams

35 36

# How to test a loop structure program

- For the control flow testing in the software including a loop, the following criteria are usually adopted instead of C0/C1 coverage measures.
  - · Skip the loop.
  - · Only one pass through the loop.
  - Typical times m passes through the loop
  - n, n-1, n+1 passes through the loop
    - n is maximum number, m is typical number (m<n)
- Example: 6 cases based on boundary-value analysis:

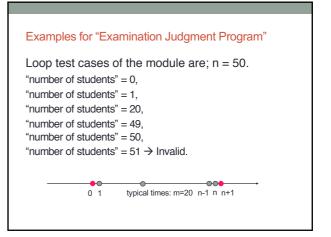

#### Examples for "Examination Judgment Program"

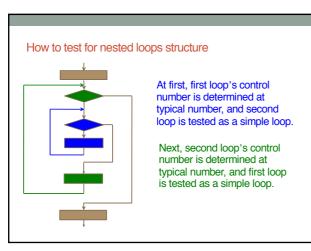

- □ Input two subjects scores, Mathematics and Physics, for each member of one class.
  - The input form is "tabular form".
- Class members can be allowed only 0 (zero) through 50.
- Output/Print out the "Examination result report for a class".
  - The output form is also "tabular form" that has the columns such as student name, scores (Math., Physics), passed or failed.

37 38

# Start Get "number of students" counter = zero Examination Judgment Program" Exercise: Create the test cases using the criteria two pages before based on the following assumptions. 1. "Examination Judgment program" are already tested. 2. Input data of this module are already checked, and valid. Print out "examination result report for a class".

39 40

#### 2.4. Combination of Black/White Box test

- Advantage of Black box
  - · Encompassing test based on external specification
- · Very powerful and fundamental to develop high-quality software
- · Advantage of White box
  - If any paths/flows don't appear in the written specifications, the paths/flows might be missed in the encompassing tests => White hox test
    - for data of more than two years before => alternative paths
  - "0 =< score =< 100" => code: "if 0 =< score " and "if score =< 100"

41 42

### How to carry out efficient and sufficient test

- · First, carry out tests based on the external specifications
  - · If all test cases are successful
  - => All external specifications are correctly implemented
- · Second, carry out tests based on the internal specifications
  - Add test cases to execute the remaining paths/flow, within external specifications
  - If all test cases are successful with coverage = 100%
     => All functions specified in the external specification are successfully implemented without any redundant codes

2.5. JUnit

- A tool for test-drivent development (junit.org)
- JUnit test generators now part of many Java IDEs (Eclipse, BlueJ, Jbuilder, DrJava)
- \* XUnit tools have since been developed for many other languages (Perl, C++, Python, Visual Basic, C#, ...)

43 44

44

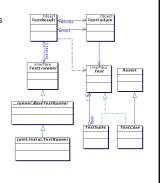

#### Why create a test suite?

- · Obviously you have to test your code—right?
  - You can do ad hoc testing (running whatever tests occur to you at the moment), or
- You can build a test suite (a thorough set of tests that can be run at any time)
- Disadvantages of a test suite

  - It's a lot of extra programming
     True, but use of a good test framework can help quite a bit
  - You don't have time to do all that extra work
  - False! Experiments repeatedly show that test suites reduce debugging time more than the amount spent building the test suite
- Advantages of a test suite
  - · Reduces total number of bugs in delivered code
  - · Makes code much more maintainable and refactorable

#### Architectural overview

- · JUnit test framework is a package of classes that lets you write tests for each method, then easily run those tests
- TestRunner runs tests and reports TestResults
- You test your class by extending abstract class TestCase
- To write test cases, you need to know and understand the **Assert** class

45 46

#### Writing a TestCase

- To start using JUnit, create a subclass of *TestCase*, to which you add test methods
- Here's a skeletal test class:

import junit.framework.TestCase;
public class TestBowl extends TestCase {

} //Test my class Bowl

- Name of class is important should be of the form *Test*MyClass or MyClass*Test*
- This naming convention lets TestRunner automatically find your test classes

# Writing methods in TestCase

- Pattern follows *programming by contract* paradigm:
  Set up **preconditions**Exercise functionality being tested
  Check **postconditions**

Things to notice:

- Specific method signature public void *test*Whatever()
- Allows them to be found and collected automatically by JUnit Coding follows pattern
- Notice the assert-type calls...

47 48

#### Assert methods

- · Assert methods dealing with floEach assert method has parameters like these: message, expected-value, actual-value
- · ating point numbers get an additional argument,
- · Each assert method has an equivalent version that does not take a message - however, this use is not recommended because:
  - · messages helps documents the tests
  - · messages provide additional information when reading failure logs

#### Assert methods

- assertTrue(String message, Boolean test)
- assertFalse(String message, Boolean test)
- assertNull(String message, Object object)
- assertNotNull(String message, Object object)
- assertEquals(String message, Object expected, Object actual) (uses equals method)
- assertSame(String message, Object expected, Object actual) (uses == operator)
- assertNotSame(String message, Object expected, Object

49 50

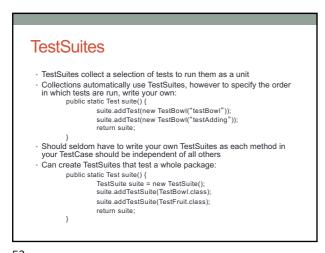

#### More stuff in test classes

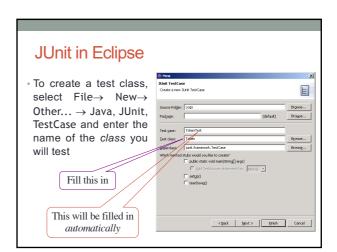

- · Suppose you want to test a class Counter
- public class CounterTest extends junit.framework.TestCase {
- · This is the unit test for the Counter class
- public CounterTest() { } //Default constructor
- protected void setUp()
  - Test fixture creates and initializes instance variables, etc.
- protected void tearDown()
- Releases any system resources used by the test fixture
- public void testIncrement(), public void testDecrement()
  - These methods contain tests for the Counter methods increment(), decrement(), etc.
  - · Note capitalization convention

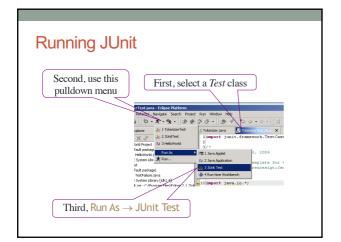

```
JUnit tests for Counter
```

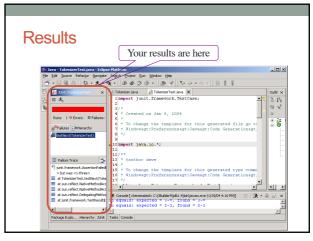

```
public class CounterTest extends junit.framework.TestCase {
   Counter counter1; public CounterTest() { } // default constructor
   protected void setUp() {    // creates a (simple) test fixture
    counter1 = new Counter();
                                                                      Note that each test begins
   public void testIncrement() {
                                                                      with a brand new counter
       assertTrue(counter1.increment() == 1);
assertTrue(counter1.increment() == 2);
                                                                     This means you don't
                                                                     have to worry about the
order in which the tests
   public void testDecrement() {
  assertTrue(counter1.decrement() == -1);
```

51 52

55 56

# Unit testing for other languages

- · Unit testing tools differentiate between:
  - · Errors (unanticipated problems caught by exceptions)
  - · Failures (anticipated problems checked with assertions)
- · Basic unit of testing:
- · CPPUNIT\_ASSERT(Bool) examines an expression
- · CPPUnit has variety of test classes (e.g. TestFixture)
  - Inherit from them and overload methods

# Another example: sqrt

// throws: IllegalArgumentException if x < 0</pre> // returns: approximation to square root of x public double  $\mathsf{sqrt}(\mathsf{double}\ x)$ 

> What are some values or ranges of X that might be worth testing

- □ x < 0 (exception thrown)
- $\square$  X  $\ge$  0 (returns normally)
- $\square$  around x = 0 (boundary condition)
- $\square$  perfect squares (**sqrt**(**x**) an integer), non-perfect squares
- $\square$  x < sqrt(x), x > sqrt(x)
- $\square$  Specific tests: say  $x = \{-1, 0, 0.5, 1, 4\}$

58 57

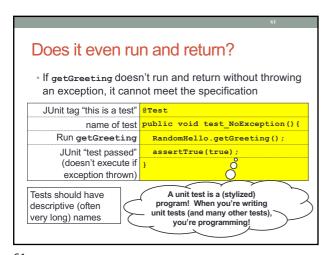

#### **Subdomains**

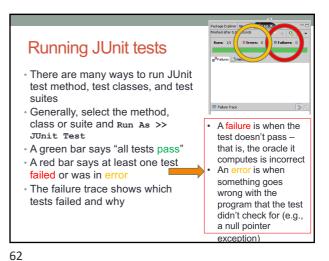

- · Many executions reflect the same behavior for sqrt, for example, the expectation is that
  - all  $\mathbf{x}$  <  $\mathbf{0}$  inputs will throw an exception
  - all x ≥ 0 inputs will return normally with a correct answer
- By testing any element from each subdomain, the intention is for the single test to represent the other behaviors of the subdomain – without testing them!
- · Of course, this isn't so easy even in the simple example above, what about when x overflows?

#### Testing RandomHello

- "Create your first Java class with a main method that will randomly choose, and then print to the console, one of five possible greetings that you define."
- We'll focus on the method getGreeting, which randomly returns one of the five greetings
- We'll focus on black-box testing we will work with no knowledge of the implementation
- · And we'll focus on unit testing using the JUnit framework
- · Intermixing, with any luck, slides and a demo

59

```
Does it return one of the greetings?

• If it doesn't return one of the defined greetings, it cannot satisfy the specification

@Test
public void testDoes_getGreeting_returnDefinedGreeting() {
    String rg = RandomHello.getGreeting();
    for (String s : RandomHello.greetings) {
        if (rg.equals(s)) {
            assertTrue(true);
            return;
        }
    }
    fail("Returned greeting not in greetings array");
}
```

```
Don't forget that
                                            Eclipse can help you
A JUnit test class
                                            get the right import
                                              statements - use
                                             Organize Imports
(Ctrl-Shift-O)
 import static org.junit.Assert.
 public class RandomHelloTest() {
  public void test_ReturnDefinedGreeting() {
   @Test
  public void test EveryGreetingReturned() {
                 ☐ All @Test methods run when
                   the test class is run
                 ☐ That is, a JUnit test class is a
                    set of tests (methods) that
                    share a (class) name
```

63 64

```
What about a sleazy developer?

if (randomGenerator.nextInt(2) == 0) {
    return(greetings[0]);
} else
    return(greetings[randomGenerator.nextInt(5)]);

| Flip a coin and select either a random or a specific greeting
| The previous "is it random?" test will almost always pass given this implementation
| But it doesn't satisfy the specification, since it's not a random choice
```

```
A JUnit test suite
import org.junit.runner.RunWith;
                                                   ☐ Define one suite for each
import org.junit.runners.Suite;
                                                      program (for now)
                                                   ☐ The suite allows multiple
@RunWith(Suite.class)
@Suite.SuiteClasses({
   RandomHelloTest.class,
                                                      test classes – each of
                                                      which has its own set of
                                                      @Test methods — to be
                                                      defined and run together
public class AllTests {
                                                   Add tc.class to the
  // this class remains completely
// empty, being used only as a
// holder for the above
                                                      @Suite.SuiteClasses
                                                      annotation if you add \boldsymbol{a}
                                                      new test class named to
  // annotations
                                                   ■ So, a JUnit test suite is a
                                                      set of test classes (which
                                                      makes it a set of a set of
                                                      test methods)
```

67 68

#### JUnit assertion methods

causes the current test to fail		
fail()	immediately	
assertTrue(tst)	if tst is false	
assertFalse(tst)	if test is true	
assertEquals(expected, actual)	if expected does not equal actual	
assertSame(expected, actual)	if expected != actual	
assertNotSame(expected, actual)	if oracle == actual	
assertNull(value)	if value is not null	
assertNotNull(value)	if value is null	

- Can add a failure message: assertNull("Ptr isn't null", value)
- $\boldsymbol{\cdot}$  expected is the oracle remember this is the first (leftmost) param
- The table above only describes when to fail what happens if an assertion succeeds? Does the test pass?

ArrayIntList: example tests

- High-level concept: test behaviors in combination
  - Maybe add works when called once, but not when call twice
  - Maybe add works by itself, but fails (or causes a failure) after calling remove

69 70

#### A few hints: data structures

• Need to pass lots of arrays? Use array literals
public void exampleMethod(int[] values) { ... }
...
exampleMethod(new int[] {1, 2, 3, 4});

exampleMethod(new int[] {5, 6, 7});
• Need a quick ArrayList?

List<Integer> list = Arrays.asList(7, 4, -2, 3, 9, 18);

 A few general hints

- Test one thing at a time per test method
  - 10 small tests are much better than one large test
- Be stingy with assert statements
  - The first assert that fails stops the test provides no information about whether a later assertion would have failed
- Be stingy with logic
- Avoid try/catch if it's supposed to throw an exception, use expected= ... if not, let JUnit catch it

71 72

Test case dangers

- · Dependent test order
  - If running Test A before Test B gives different results from running Test B then Test A, then something is likely confusing and should be made explicit
- Mutable shared state
  - Tests A and B both use a shared object if A breaks the object, what happens to B?
    - · This is a form of dependent test order
  - We will explicitly talk about invariants over data representations and testing if the invariants are ever broken

# More JUnit

- Timeouts don't want to wait forever for a test to complete
- · Testing for exceptions GTest(expected = ArrayIndexOutOfBoundsException.class)
  public void testBadIndex() {
   ArrayIntList list = new ArrayIntList();
- Setup [teardown] methods to run before [after] each test case method [test class] is called

74 73

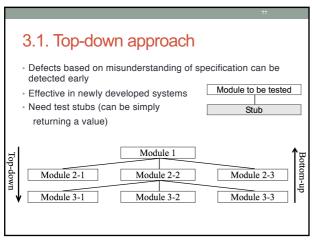

#### Content

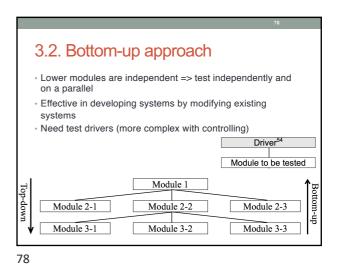

- 1. Testing overview
- 2. Unit Test
- 3. Integration Test

Driver<sup>54</sup> Module to be tested 3. Integration test · Examine the interface between modules as well as the input and output Stub/Driver: · A program that simulates functions of a lower-level/upperlevel module Module 1 Module 2-1 Module 2-2 Module 2-3 Module 3-1 Module 3-2 Module 3-3

76 75

list.get(4); // this should raise the exception
// and thus the test will pass

# 3.3. Other integration test techniques

- Big-bang test

77

- · Wherein all the modules that have completed the unit tests are linked all at once and tested
- Reducing the number of testing procedures in smallscale program; but not easy to locate errors
- Sandwich test
  - Where lower-level modules are tested bottom-up and higher-level modules are tested top-down

3.4. Regression test

"When you fix one bug, you introduce several new bugs"

- Re-testing an application after its code has been modified to verify that it still functions correctly
  - · Re-running existing test cases
  - Checking that code changes did not break any previously working functions (side-effect)
- · Run as often as possible
- · With an automated regression testing tool

79 80
